Building Kieler without Eclipse

If you want to build a Kieler product or the KiCo command line tool, you will need to use maven to build the project.

Requirements

- Java 11
- Maven
- Python 2.7 (Only for building the CLI. Must be available as python command, check conflicts with Python 3)

Commands

Commands should run from the semantics root directory.

If Java 11 is not your default java command prepend the following command (Linux) to set the java version: **JAVA_HOME=/usr/lib/jvm/java-11-openjdk-amd64/**

Hence it may look like: JAVA_HOME=/your/path/to/java mvn -f build/pom ...

It is recommended to add -T 2 as parameter to the following commands to speed up the build. However, it might be not helpful in some situations as the build log will be scrambled due to the parallel build threads.

Command	Effect
mvn -f build/pom.xml clean package -P semantics.test	Builds all plugins and CLI. CLI tools are located in build/de.cau.cs.kieler.kicool.cli/target/exe or sccharts.cli respectively.
mvn -f build/pom.xml clean integration-test - P semantics.test	Performs all tests (including CLI tests)
mvn -f build/pom.xml clean package -P semantics	Builds all plugins and creates the updatesite in build/de.cau.cs.kieler.semantics.repository/target/repository
mvn -f build/pom.xml package -P semantics. product	Builds the Kieler product and CLI. By default the build will use the plugins from the nightly updatesite, not the locally built plugins! Change the <i>kieler.semantics.updatesite</i> property in <i>build/pom.xml</i> to a file url (file://your/path/to/updatesite) leading to updatesite mentioned above. Do not commit this change!
